

Dr. Miller received a phone call from Rick Routledge at SFU who was studying Rivers Inlet sockeye salmon and trying to determine what might be causing their declines in abundance. He noted that his student, Nicole, had collected out-migrating smolts at various locations along River's inlet in 2011 and noted that compared to other years, they were skinnier and looked less healthy and some were dying in the nets. He suggested that there may be parallels with what was going on in the Fraser, and was interested in getting his fish "tested" for the genomic signature Miller's lab had identified as associated with premature mortality of adults returning to the Fraser River to spawn. Unfortunately, his samples were not collected in a way that would permit genomic analysis, but Dr. Miller suggested that she could test them for parvovirus, which is a candidate virus.

On Sept 29, 2011, Nicole, Rick Routledge's student, brought to the Molecular Genetics Laboratory 48 sockeye salmon smolts collected from Rivers Inlet. She worked with Derek Menard and Cowan Belanger, co-op students in the Molecular Genetics Lab, to dissect these fish. We took anterior kidneys and placed them in rows of 8 tubes on ice, and these were transferred to the -80 freezer when filled. Nicole was taking heart and stomach samples from each fish and placing the hearts in individually labelled whirl packs and stomachs in scintillation vials with 95% ethanol, also individually labelled. Well number, bag number, arbitrary fish number, length and weight were recorded by Nicole, but not give to us. The arbitrary fish numbers should be the same between our samples and hers. The carcasses were placed into individually labelled bags as well. She had brought perhaps 200 carcasses, but only 48 were dissected. She took the undissected carcasses back with her and left those that had been dissected in the molecular genetics lab in a -20 freezer.

On Oct 12 (or thereabouts), Dr. Miller received a phone call that they wanted the carcasses back, and they came and picked them up that afternoon.

On Oct 13, Cowan Belanger placed the frozen kidney samples in a trizol homogenate that enables us to extract both DNA and RNA from the sample. The Rivers Inlet samples were placed on a 96-well tray along with 34 herring samples that had been collected in the Strait of Georgia and which we intended to test for parvovirus. There was one glitch with these homogenates in that one of the steps involving incubation with BCP was incubated for 45 minutes as opposed to the recommended 10 minutes. Later analyses of the extracted DNA and RNA did not suggest that this caused significant harm to the samples. DNA was extracted from these homogenates on that day. Cowan took the RNA containing aqueous layer off the top of the trizol homogenates and placed them into three separate trays—i.e. they could be extracted 3 times.

On Oct 17, Angela Schulze, a technician in the Molecular Genetics Lab, extracted RNA from one of the three trays containing the aqueous layer of the Trizol homogenate. Quantitation of the RNA extraction showed decent yields of RNA (around 300-500 ng/ $\mu$ l), although a few samples were very low. Our students had noted that some samples

were in very poor condition, possibly long dead and degraded. Unfortunately they did not take notes that would reveal which fish these were. RNA degrades very rapidly after death.

We have not yet analysed these samples for parvovirus, as we had other deadlines to meet and they were not deemed "high priority" in our lab. We did not know when we obtained these samples that they were being sent out for ISA analysis, but Dr. Miller did suggest that if they were interested in a full workup on disease that they contact a diagnostic lab to do those analyses.

The RNA from these kidney samples will be sent to the OIE testing lab in Moncton, care of Nellie Gagne, on Monday, Oct 24, 2011.

A handwritten signature in black ink, appearing to read "Tim M. Dene".
